2. Genetic Engineering of Microbial Reporter Cells. Although unmodified bacteria have been used as biosensors, based on changes in natural bioluminescence as cells grow, genetic engineering of microbial cells is extensively employed to rationally produce dose-dependent signals to predetermined environmental stimuli [22, 23]. Typical engineering methods include fusion of a reporter gene system to promoters from selected stress-response regions, resulting in specific cell growth and easily ...

Projects aim to discover the molecular basis for these processes using both classical and cutting-edge techniques. These include plasmid manipulation, genetic complementation, mutagenesis, PCR, DNA sequencing, enzyme assays, and gene expression studies. Instruction and practice in written and oral communication are also emphasized.

Identifying coregulated genes can also employ lacZ fusions as a reporter system. In this case, lacZ gene fusions are constructed randomly throughout the bacterial chromosome, usually with the aid of a transposable element that can create a lacZ fusion when it inserts in a gene in the correct orientation.

From this microbe scientists isolated the enzyme Taq polymerase, which is now used in the powerful experimental technique, Polymerase chain reaction (PCR). Additionally the development of recombinant DNA technology through the use of bacteria has led to the birth of modern genetic engineering and biotechnology.
